FIBER SOURCING ANALYSIS FOR THE GLOBAL PULP AND PAPER INDUSTRY

Background:

IIED commissioned Wood Resources International Ltd to undertake this study for the "Sustainable Paper Cycle" project. The study required a snapshot evaluation of current sources of fiber to the global pulp and paper industry.

Objective:

The Objective of this task, the first of two to be undertaken by Wood Resources International Ltd., was to construct a global model, on a country by country basis, of the current sources of fiber used in the production of pulp.

Methodology:

Using public data sources such as the U.N. Food and Agricultural Organization (FAO), Pulp and Paper International Magazine, and a purchased data base of deinked pulp capacity and estimated production, we were able to estimate the total volume of pulp produced in each country for 1993. We then subtracted deinked pulp production, and pulp based on non-wood fibers such as bagasse or straw, to determine the 1993 production of wood based pulp. Total wood pulp production was then allocated by pulping process (chemical, semi-chemical, mechanical) based on either actual production by process, or capacity by process, to derive a total wood fiber demand in Oven Dried Metric Tonnes for 1993.

Finally, we researched each country to determine the characteristics of wood used in pulp production. Wood supply was classified as being conifer or hardwood, roundwood or manufacturing residue. Finally the total volume of wood used was allocated to various categories of forest types, depending on the source of the material. Although it is not our intention to impose this classification scheme on follow-on research, it was necessary to establish a working classification scheme in order to consolidate and compare data. Eleven categories were established. They are listed below, and defined on page ii and iii.

Forest Categories

Hardwood Original Forest

Hardwood Indigenous Plantations

Hardwood Exotic Plantations

Hardwood Managed Natural Regeneration

Hardwood Un-Managed Natural Regeneration

Mixed Tropical Hardwood

Conifer Original Forest

Conifer Indigenous Plantations

Conifer Exotic Plantations

Conifer Managed Natural Regeneration

Conifer Un-Managed Natural Regeneration

FIBER SOURCING ANALYSIS FOR THE GLOBAL PULP AND PAPER INDUSTRY

Forest Categories:

Original Forest - A forest generally not yet harvested by man for forest products, or cleared for agricultural use.

Original forests remain in several regions of the world. In the northern hemisphere, they are represented primarily by the boreal conifer (*Picea-Abies-Pinus-Larix*) forests of Russia, Canada, northern China, and parts of the U.S. Northwest. In the southern hemisphere, they are represented by some tropical hardwood forests in the countries of central South America, Equatorial Africa, and Southeast Asia. Although some natural regeneration forests exist in tropical hardwood areas, the forest category - Mixed Tropical Hardwood - utilized in this analysis is a sub-set of Hardwood Original forests. In southern hemispheric countries such as Chile, Argentina, and Australia, some temperate hardwood forests (*Nothofagus*, *Eucalyptus*) may also be classified as original forest.

Indigenous Plantations (I) - Forests of local species planted after harvesting or site preparation activities.

Exotic Plantations (E) - Forests of exotic species planted after harvesting or site preparation activities

Natural Regeneration - At least second-growth forests regenerated from seed or coppice.

Natural regeneration forests are the largest source of wood fiber to the global pulp and paper industry. The structure of such forests depends on regional species composition, and ecological conditions. Natural regeneration forests may be under even-aged, uneven-aged, or no management.

In Europe, natural regeneration forests generally consist of mixed temperate conifer and hardwood species such as *Picea Abies*, *Pinus Sylvestris*, *Abies spp.*, *Quercus spp.*, and *Fagus Sylvatica*. In some areas, *Betula spp.* may also play a role, particularly in northern climates, or on former agricultural lands.

In North America, a similar but broader mixed of temperate conifer and hardwood species naturally regenerate a cut-over area. They include *Pinus spp.*, *Abies spp.*, *Picea spp.*, *Pseudotsuga Men.*, *Tsuga spp.*, *Quercus spp.*, *Acer spp.*, *Fagus spp.*, *Betula spp.*, *Liriodendron spp.*, *Populus spp.*, *Prunus spp.*, *Fraxinus spp.*, and *Carya spp.* Russian natural regeneration forests closely resemble those of Scandinavia in the west, and those of North America, in the Russian Far East. Natural regeneration forests in Asia generally consist of low quality tropical hardwood species, and native *Eucalyptus* forests in Australia.

FIBER SOURCING ANALYSIS FOR THE GLOBAL PULP AND PAPER INDUSTRY

Managed Forests -

Forests currently under a formal forest management plan depicting such things as stand structure, age class distribution, and silvicultural prescriptions.

Other Working Definitions

ODMT:

Oven Dried Metric Tonne - 2204 pounds of fiber at 0% moisture content.

Pulp Yields:

The following average yields have been used to convert wood pulp production to wood fiber demand.

Chemical -

2.17 ODMT per tonne of pulp

NSSC/SemiChem -

1.28 ODMT per tonne of pulp

Thermo-mechanical -

1.09 ODMT per tonne of pulp

Groundwood -

1.06 ODMT per tonne of pulp

FIBER SOURCING ANALYSIS FOR THE GLOBAL PULP AND PAPER INDUSTRY

Unique Aspects of this Analysis:

"Snapshot" Analysis

The base year for our effort was 1993. The figures in this report represent our best estimates of the wood fiber used for pulp production in that year. Because it can take 50-75 years for a forest to reach biological maturity, the structure of forests in 1993 in part reflects forest management decisions that were made early in this century. This is a "snapshot" analysis, which if undertaken in 1983, or 2003 would have yielded very different results.

For example, a similar analysis in 1983 would have reflected much lower use of deinked pulp, and plantation wood fiber, and higher demand on original conifer forests. It is also likely that the percentage of managed natural regeneration forests would have been slightly lower than was estimated in 1993. If this analysis were undertaken again in 2003, we would expect to see higher levels of deinked pulp, and plantation fiber, as industrial plantations established during the 1980's throughout South America, Asia, and Africa begin to mature.

Two additional factors could change the structure of the global fiber supply in the future. They are: 1) world trade of wood fiber from producing to consuming regions and 2) the availability of land for intensive plantations.

Wood Fiber Trade

As much as 55 million cubic meters of pulpwood and wood chips are traded each year in the world. As shown on pages 6-8, the major consuming regions are Asia (net importer of 21.4 million cubic meters per year), and Europe (net importer of 6.3 million cubic meters per year). Major export regions include North America (+9.8 million cum), Russia (+6.6 million cum), and Oceania (+6.1 million cum).

Trade may be defined as either "boarder" trade, which is basically the extension of a natural procurement zone across political boundaries, or "ocean" trade, which may involve the movement of wood around the world. Trade is driven primarily by greater than freight-equalized wood cost differentials between countries. For example, it is currently cheaper for the Japanese to import hardwood woodchips from the U.S. South (CIF price of US\$ 158 per ODMT), than it is to harvest their own hardwood (chip plant price of US\$ 193 per ODMT). Unless phytosanitary (insect/disease) restrictions limit trade, the global tendency is to procure wood fiber from its cheapest source.

A unique feature of wood fiber trade in the Pacific Rim is the trade of wood in chip, rather than roundwood form. Although as much as 70% of the chips that are imported into this region are roundwood chips, as opposed to manufacturing residues, use of chips evolved from the first movements of conifer sawmill residues to Japan from the U.S. Pacific Northwest in the 1960's. In contrast, the majority of wood fiber imported into Europe (primarily Scandinavia) is imported in roundwood form.

Global trade of wood fiber is expected to modestly increase over the next 10 years as the cost differential between industrial plantation fiber, and traditional fiber sources widens. However, in the longer term, it is anticipated that primary production capacity will shift toward those countries supporting plantations due to competitive production costs, and better access to expanding markets.

Industrial Plantations

The 1970's and 1980's was a period of rapid growth in the establishment of industrial plantations as reflected by the fact that nearly 30% of global wood-based pulp production in 1993 was based on industrial plantation fiber. Growth rates for these plantations range from an average of 25-30 cubic meters per hectare per year for Eucalyptus in Brazil, to 3-5 cum/ha/year for Spruce in Scandinavia. Hardwood plantations are primarily based in the southern hemisphere and average 15-20 cum/ha/year. Conifer plantations are generally managed on a longer rotation (20-40 years), and, taking into account plantations in both the northern and southern hemisphere, average less than 10 cum/ha/year.

Using an average growth rate of 15 cum/ha/year, it is easily calculated that the world's 1993 wood fiber demand could be supplied from a total industrial plantation area of 41 million Ha. - or approximately 1.5% of the world's total closed forest area of approximately 3 billion ha. At an average growth rate of 10 cum/ha/year, 62 million ha. of industrial plantations are required. This is equal to approximately 2% of the world's closed forest area, or a land area 2.5 times the size of the U.K., but somewhat smaller than the U.S. state of Texas.

As previously mentioned, the percentage of production based on such fiber crops is expected to increase significantly in the coming decades due to the:

- + Continued withdraw of original and natural regeneration forests from industrial production,
- + Homogeneity of plantation raw material (density, fiber length, extractives), and
- + High yield, and short rotation of most industrial plantation forests.

The only constraining factor may be the availability of suitable land, which must have reasonably good soils, and abundant rainfall. Although land is less available than when industrial plantations were first established, it is anticipated that marginal agricultural land (e.g. sugar cane land), will become available in many countries over the next 10-20 years, and provide opportunities for new forest plantation investments.

Information

As far as we are aware, this is the first study that has tried to determine the source of fiber for pulp production on a global basis. As few, if any, pulp producers have any incentive to record or make public their sources of fiber, this effort is not without estimates. We have found discrepancies in published estimates of total pulp production, non-wood pulp production, and deinked pulp capacities. There is no uniform data concerning harvests by forest type for any country that we are aware of. Our work is based on our, and our contact's first-hand knowledge of forest types in each country, and the likely percentage of wood from various sources that is used in pulp production. We analyzed fiber sources in major pulp producing regions in greatest detail, and are confident that our overall assessment is an accurate reflection of global wood fiber demand in 1993.

KEY FINDINGS AND CONCLUSIONS

- The global pulp industry produced approximately 185.5 million tonnes of pulp in 1993 from approximately 1350 major pulpmill installations. Of total production, approximately 11% was based on recycled fiber as a result of de-inking facilities. An additional 8% was based on non-wood fiber such as straw, bagasse and bamboo. Total pulp based on virgin wood fiber was estimated at 149.8 million tonnes, or approximately 81% of total production.
- By far the largest single non-wood pulping fiber used on a global basis is straw - accounting for nearly 47% of all non-wood fiber consumed for pulp production in 1993. Other non-wood fibers include bagasse (12%), bamboo (6%), and a wide assortment of "other" fibers ranging from rags to seaweed. Non-wood pulp in Asia accounts for approximately 90% of all non-wood pulp manufactured world-wide, and accounted for nearly 40% of the fiber based pulp manufactured in that region in 1993.
- The production of wood pulp required approximately 277 million ODMT of wood fiber in 1993, or approximately 618 million cubic meters of wood. Nearly one third of this volume (31%) consisted of hardwood species such as Oak (*Quercus*), Birch (*Betula*), and Maple (*Acer*). The balance consisted of conifer species such as Pine (*Pinus*), Spruce (*Picea*), and Fir (*Abies*). Approximately 37% of wood consumption was in chip form, from manufacturing residues (27%), or off-site chipping operations (10%). The balance, 63%, consisted of roundwood pulpwood supply.
- Trade of wood fiber for pulp production was estimated for 1993 at 50 million cubic meters, or 8% of total wood fiber consumption. This is down from 10-12% in 1990-1992 as falling pulp and paper prices reduced operating rates and margins, and made typically higher cost off-shore fiber less attractive to traditional import-oriented producers.
- On a global basis, Managed Natural Regeneration forests account for the largest source of wood used in the production of pulp (39% of hardwood consumed, 36% of conifer consumed, and 37% of total wood fiber). These forests are typically found in W. Europe, Scandinavia, and the United States, which combined, account for nearly 60% of global wood based pulp production.
- Although Exotic plantations virtually support wood based pulp production in Africa, Oceania, and South America, their share of total wood based pulp production is only 19% for hardwood, 7% for conifer, and 11% of total wood pulp production. Plantations of indigenous species, in fact, account for a larger share (18%), of global wood pulp production.

KEY FINDINGS AND CONCLUSIONS Cont.

- Mixed Tropical Hardwood forests (often referred to as "Tropical Rainforests") and Original Hardwood Forests (such as the native hardwood forests of Chile, and the native Eucalyptus forests of Australia), support only 2% of global wood based pulp capacity. Original Conifer forests, conversely, are a significant source of raw material, and were estimated in 1993 to provide approximately 15% of the fiber used to produce wood based pulp on a global basis.
- 1993 fiber supply to the wood-based pulp industry by major forest type was estimated as follows:

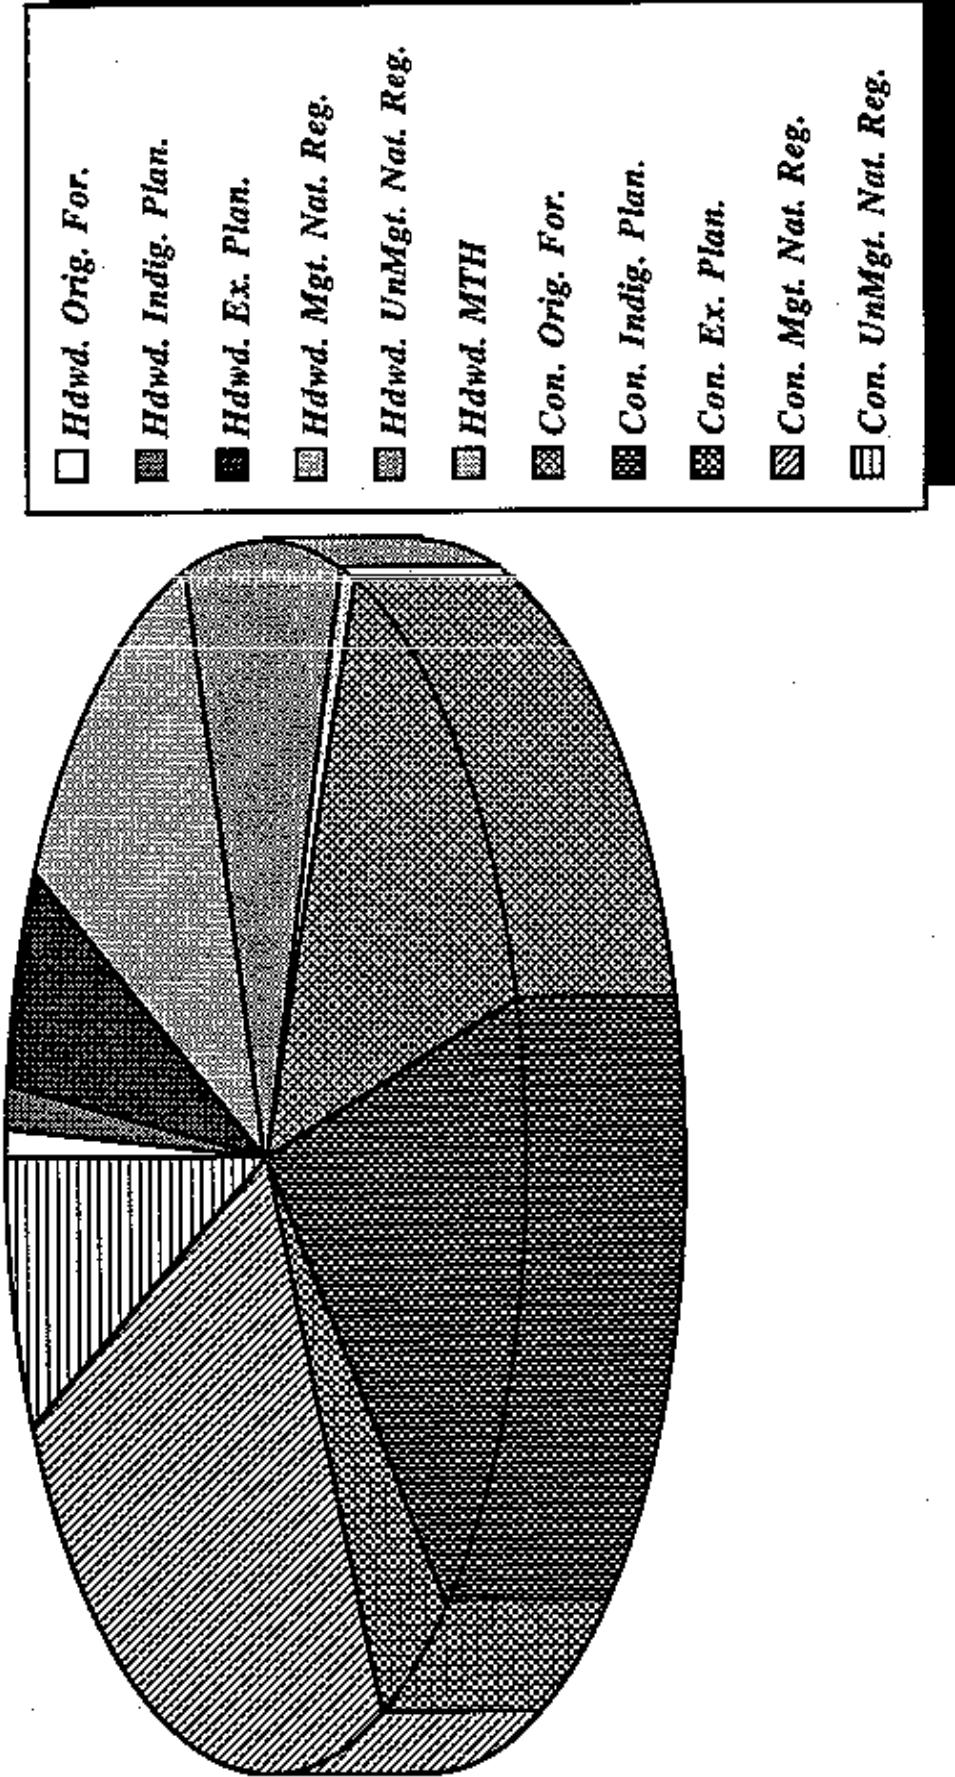

<u>Forest Type</u>	<u>% of Total</u>
Hardwood Original Forest	1

REGION: CIS

COUNTRY: RUSSIA

Pulp Industry 1993

Number of Pulpmills	50
Total Pulp Production (1000 tonnes)	5501
Deinked Pulp Production (1000 tonnes)	(147)
Virgin Fiber Pulp Production (1000 tonnes)	5354
Non-Wood Pulp Production (1000 tonnes)	(0)
Bamboo	Hemp
Bagasse	Cotton
Straw	Reed
Other	
Wood-Based Pulp Production (1000 tonnes)	5354
Derived Wood Fiber Demand (1000 ODMT)	10457

Wood Supply Characteristics (Cum/ODMT = 2.5)

Conifer - 82%	Hardwood - 18%
Roundwood - 77%	Residues - 23% (Manf.)
<u>Forest Type</u>	<u>Est. Supply 1993 (1000 cum)</u>
Conifer - Original Forest	19750
Conifer - Mgt. Natural Regeneration	2500
Hardwood - UnMgt. Natural Regeneration	3700
TOTAL	25950
